Communicated by Alphonse P. Magnus
Received February 6, 1990; revised June 29. 1990

We are concerned with polynomials $\left\{p_{n}^{1 / 1)}\right.$; that are orthogonal with respect to the Sobolev inner product

$$
\langle f, g\rangle ;-\int f g d \varphi+i \int f^{\prime} g^{\prime} d \psi
$$

where $i$ is a non-negative constant. We show that if the Borel measures $d \varphi$ and $d \psi$ obey a specific condition then the $p_{n}^{\prime \cdot 1} s$ can be expanded in the polynomials orthogonal with respect to $d \varphi$ in such a manner that. subject to correct normalization, the expansion coefficients, except for the last, are independent of $n$ and are themselves orthogonal polynomials in $;$. We explore several examples and demonstrate how our theory can be used for efficient evaluation of Sobolev-Fourier coefficients. 1991 Academic Press. Itc.

## 1. Introduction

Orthogonality in Sobolev spaces has attracted considerable attention in recent decades $[1,3-6,8,10,17-20]$. In the present paper we propose to approach that oft-discussed problem from a different point of view.

Throughout, the term "Borel measure" is used to refer to positive Borel measures $\varphi$ on the real line, satisfying the conditions

$$
\begin{equation*}
\left|\int_{x}^{\infty} x^{k} d \varphi(x)\right|<\infty, \quad k=0,1,2, \ldots \tag{1.1}
\end{equation*}
$$

(finite moments) and

$$
\begin{equation*}
\int_{-x}^{\infty} p(x) d \varphi(x)>0 \tag{1.2}
\end{equation*}
$$

for each polynomial $p$ that is non-negative for all real $x$ and not identically zero (positive definiteness).

Thus, if $d \varphi$ and $d \psi$ are two Borel measures and $\lambda$ is a positive constant, the Sobolev space $W_{2}^{1}[(-\infty, x), d \varphi, d \psi]$ with the inner product

$$
\begin{equation*}
\langle f, g\rangle_{:}:=\int_{-\infty}^{\infty} f(x) g(x) d \varphi(x)+\lambda \int_{-\infty}^{\infty} f^{\prime}(x) g^{\prime}(x) d \psi(x) \tag{1.3}
\end{equation*}
$$

contains the space of all polynomials and it makes sense to study polynomials that are orthogonal with respect to $\langle\cdot, \cdot\rangle_{i}$. Specifically, we say that the $n$th degree polynomial $p_{n}^{(i)}, p_{n}^{(i)} \not \equiv 0$, is Sobolev-orthogonal if

$$
\begin{equation*}
\left\langle x^{k}, p_{n}^{(\lambda)}\right\rangle_{i}=0, \quad k=0,1, \ldots, n-1 . \tag{1.4}
\end{equation*}
$$

Note that, of course, the parameter $\lambda$ can be absorbed into $d \psi$. This, however, will defeat one of the purposes of our investigation: to examine the dependence of $p_{n}^{(i)}$ upon $\hat{\lambda}$. Note further that the condition (1.2) is equivalent to the requirement that the support of $d \varphi$ should contain an infinite number of points. In other words, we do not allow discrete measures of the form

$$
\int_{-\infty}^{\infty} f(x) d \theta(x)=\sum_{k=0}^{n} \theta_{k} f\left(x_{k}\right) .
$$

Much is already known about Sobolev-orthogonal polynomiais. Some of the familiar properties of the "standard" orthogonal polynomials can be translated intact into the more general framework, with obvious amendments: for example, among all $n$th degree polynomials with a fixed coefficient of $x^{n}, p_{n}^{(i)}$ minimizes the norm that is induced by $\langle\cdot, \cdot\rangle_{i}[10]$. Expansion of functions in $\left\{p_{n}^{(i)}\right\}_{n=0}^{x}$ with respect to the inner product (1.3) is also a straightforward extension of the classical theory-cf. $[1,4,18]$ -
and it has attracted recent attention [6] because of its relevance to the analysis of spectral methods for partial differential equations. However, most properties fail or need be paraphrased to a large extent: three-term recurrence relations are, of course, lost, as is the Christoffel-Darboux formula. More importantly, zeros of $p_{n}^{(,)}$need not belong to the support of the underlying measures [1].

Two sets of measures have been investigated in some detail:

$$
\varphi(x)=\psi(x)= \begin{cases}-1: & x<-1 \\ x: & -1 \leqslant x \leqslant 1 \\ 1: & 1<x\end{cases}
$$

(the Legendre case) and

$$
\varphi(x)=\psi(x)= \begin{cases}-1: & x<0 \\ -e^{x}: & 0 \leqslant x\end{cases}
$$

(the Laguerre case). This led to the derivation of explicit forms, recurrence relations, and localisation of zeros $[1,4,8$ ].

Another problem that has recently received some attention is that of Sobolev orthogonality with atomic measures, inclusive of the case of $d \psi$ being supported on a finite set $[17,20]$. Although, strictly speaking, it ceases in that case to be a Borel measure, $\langle\cdot, \cdot \cdot\rangle$, is, nonetheless, a positive inner product, as long as $d \varphi$ is a genuine measure.

In the present paper we study the expansion of $p_{n}^{(\lambda)}$ in the basis spanned by $p_{0}, p_{1}, \ldots, p_{n}$, where the $p_{n}$ 's are orthogonal (in the usual sense) with respect to the inner product defined by the first Borel measure, $d \varphi$. In other words, $p_{n} \equiv D_{n} p_{n}^{(0)}$, where $D_{n} \not \equiv 0$ is a constant. Naturally, an expansion of the form

$$
p_{n}^{(\lambda)}(x)=\sum_{k=1}^{n} r_{k}^{(n)}(\lambda) p_{k}(x), \quad n=1,2, \ldots
$$

(it follows from (1.4) that $r_{0}^{(n)} \equiv 0$ for $n>0$ ), is always well defined. However, it turns out that, subject to an extra condition being imposed on the measures $\{d \varphi, d \psi\}$ and under correct normalization, the coefficient $r_{k}^{(n)}$ depends only on its subscript for all $k=0,1, \ldots, n-1$. In other words, subject to the $p_{k}$ 's being correctly normalized, there exist $x_{1}(\lambda), x_{2}(\lambda), \ldots$ such that

$$
p_{n}^{(i)}(x)=\sum_{k=1}^{\prime-1} x_{k}(i) p_{k}(x)+r_{n}^{(n)}(i) p_{n}(x)
$$

for every $n=1,2, \ldots$. This leads inter alia to a recurrence relation of the form

$$
p_{n+1}^{(\hat{\lambda})}(x)-p_{n}^{(\hat{\lambda})}(x)=\sigma_{n}(\dot{\lambda})\left(p_{n+1}(x)-p_{n}(x)\right),
$$

where $\sigma_{n}$ can be written explicitly in terms of the $x_{k}$ 's. The last identity can be employed to evaluate efficiently expansions of $W_{2}^{1}$ functions in Sobolevorthogonal polynomials. Section 2 of the present paper is devoted to the formal derivation of the aforementioned results, whereas in Section 3 we study specific examples of $\{d \varphi, d \psi\}$ that obey the required condition and in Section 6 we present the fast algorithm for the evaluation of FourierSobolev coefficients.

Section 4 is concerned with an extension of our framework, whereby $p_{n}^{(\lambda)}$ can be expanded in $p_{n}$ 's with $m$ and $n$ of the same parity and the coefficients of this expansion, except for the last, are independent of $n$.

The coefficients $\alpha_{k}$ (note that we can remove the superscript) turn out to be themselves orthogonal polynomials, and we devote Section 5 to the determination of underlying measures.

## 2. Coherent Pairs

Let $d \varphi$ and $\alpha \psi$ be two Borel measures and $\lambda \geqslant 0$ a given constant. We recall the definitions (1.3) and (1.4) of a Sobolev inner product $\langle\cdot, \cdot\rangle_{\dot{A}}$ and a Sobolev-orthogonal polynomial $p_{n}^{(i)}$. Moreover, we let $p_{n}$ and $q_{n}$ denote orthogonal polynomials with respect to $d \varphi$ and $d \psi$, respectively:

$$
\begin{aligned}
& \int_{-\infty}^{\infty} p_{m}(x) p_{n}(x) d \varphi(x)=\dot{\delta}_{m, n} c_{n}, \\
& \int_{-\infty}^{\infty} q_{m}(x) q_{n}(x) d \psi(x)=\delta_{m, n} e_{n}, \quad m, n=0,1, \ldots,
\end{aligned}
$$

where $\delta_{m, n}$ is the delta of Kronecker. The $p_{n}$ 's are normalized so that $p_{n}^{(0)} \equiv p_{n}$. We define numbers $d_{m, n}=d_{n, m}$ by

$$
d_{m, n}=\int_{-\infty}^{\infty} p_{m}^{\prime}(x) p_{n}^{\prime}(x) d \psi(x), \quad m, n=0,1, \ldots
$$

Obviously, since $\left\{p_{0}, p_{1}, \ldots, p_{n}\right\}$ span the linear space of $n$th degree polynomials, there exist $r_{0}^{(n)}, r_{1}^{(n)}, \ldots, r_{n}^{(n)}$ such that

$$
\begin{equation*}
p_{n}^{(i)}(x)=\sum_{k=0}^{n} r_{k}^{(n)} p_{k}(x) . \tag{2.1}
\end{equation*}
$$

Of course, the $r_{k}$ 's are functions of $\lambda$. In fact, it will be shown below that, under appropriate normalization, the $r_{k}$ 's are polynomials in $\lambda$. We note that, since (1.4) with $k=0$ implies that

$$
\int_{-x}^{\infty} p_{n}^{(i)}(x) d \varphi(x)=0, \quad n \geqslant 1,
$$

necessarily $r_{0}^{(n)}=0$ for all $n \geqslant 1$ and the sum extends from $k=1$.
According to the definition (1.4), $p_{n}^{(2)}$ annihilates $p_{0}, \ldots, p_{n-1}$ in the Sobolev inner product. We utilize the expansion (2.1) to obtain $n-1$ homogeneous linear equations in the $n$ unknowns $r_{1}^{(n)}, r_{2}^{(n)}, \ldots, r_{n}^{(n)}$ :

$$
\begin{aligned}
& \left\langle p_{n}^{(\lambda)}, p_{m}\right\rangle_{\lambda} \\
& \quad=\sum_{k=1}^{n} r_{k}^{(n)}(\lambda)\left\{\int_{-\infty}^{*} p_{k}(x) p_{m}(x) d \varphi(x)+i \int_{\infty}^{\infty} p_{k}^{\prime}(x) p_{m}^{\prime}(x) d \psi(x)\right\} \\
& \quad=c_{m} r_{m}^{(n)}(\lambda)+i \sum_{k=1}^{n} d_{k, m} r_{k}^{(n)}(\lambda)=0, \quad m=1,2, \ldots, n-1 .
\end{aligned}
$$

We complement this system with the normalizing equation

$$
c_{n} r_{n}^{(n)}(\lambda)+i \sum_{k=1}^{n} d_{k . n} r_{k}^{(n)}(\lambda)=\omega(\lambda),
$$

where $\omega$ will be assigned a specific value in the sequel. Reverting to a vector form, we have the system

$$
\begin{equation*}
(\mathbf{C}+i \mathbf{D}) \mathbf{r}^{(n)}=\omega \mathbf{e}_{n}, \tag{2.2}
\end{equation*}
$$

where

$$
\mathbf{C}:=\operatorname{diag}\left\{c_{1}, c_{2}, \ldots, c_{n}\right\}, \quad \mathbf{D}:=\left(d_{k . l}\right)_{k . l}=1 \ldots, \ldots
$$

$\mathbf{r}^{(n)}:=\left[r_{1}^{(n)}, r_{2}^{(n)}, \ldots, r_{n}^{(n)}\right]^{T}$, and $\mathbf{e}_{n}$ is the $n$th unit vector. The formal solution of (2.2) by Cramer's rule is

$$
\begin{equation*}
\mathbf{r}^{(n)}=\omega(\mathbf{C}+\lambda \mathbf{D})^{1} \mathbf{e}_{n}=\omega \frac{\operatorname{adj}(\mathbf{C}+\lambda \mathbf{D})}{\operatorname{det}(\mathbf{C}+\lambda \mathbf{D})} \mathbf{e}_{n}, \tag{2.3}
\end{equation*}
$$

where $\operatorname{adj} \mathbf{B}$ is the "adjoint" matrix of $\mathbf{B}$. This motivates our choice of normalization,

$$
\omega:=\frac{\operatorname{det}(\mathbf{C}+i \mathbf{D})}{\prod_{k=1}^{n} c_{k}} .
$$

Operating on (2.3) yields at once

$$
\begin{align*}
p_{n}^{(i)}= & {\left[r_{1}^{(n)}, r_{2}^{(n)}, \ldots, r_{n}^{(n)}\right]\left[\begin{array}{c}
p_{1} \\
p_{2} \\
\vdots \\
p_{n}
\end{array}\right] } \\
& =\frac{1}{\prod_{k-1}^{n-1} c_{k}} \\
& \times \operatorname{det}\left[\begin{array}{cccccc}
c_{1}+i d_{1,1} & i d_{1,2} & \cdots & i d_{1, n} & 1 & p_{1} \\
i d d_{2,1} & c_{2}+i d_{2,2} & \cdots & i d_{2, n} & 1 & p_{2} \\
\vdots & \vdots & \ddots & \vdots & \vdots \\
i d_{n} & 1,1 & i d_{n-1,2} & \cdots & c_{n} & 1+i d_{n} \\
1, n-1 & p_{n} & 1 \\
i d_{n, 1} & i d d_{n, 2} & \cdots & i d_{n, n} & 1 & p_{n}
\end{array}\right] . \tag{2.4}
\end{align*}
$$

Note that our choice of $\omega$ implies that, indeed, $p_{n}^{(0)} \equiv p_{n}$.
The last formula is, as such, neither surprising nor very interesting for arbitrary Borel measures. Things, however, change when we confine our attention to a subset of measures that possess an important feature: We say that the pair $\{d \varphi, d \psi\}$ of Borel measures is coherent if there exist non-zero constants $C_{1}, C_{2}, \ldots$ such that, for all $k, m=1,2, \ldots, C_{k} C_{m} d_{k, m}$ is a function of $\min \{k, m\}$ only. Without much danger of confusion, we write

$$
d_{k, m}=\frac{d_{\min ; k, m i}}{C_{k} C_{m}}
$$

We renormalize the underlying polynomials

$$
C_{m} p_{m} \mapsto p_{m}, \quad C_{m} p_{m}^{(i)} \mapsto p_{m}^{(i)}, \quad m=0,1, \ldots
$$

Hence $d_{k, m} \mapsto d_{\min \{k, m ;}$ and $C_{m}^{2} c_{m} \mapsto c_{m}$. This produces the expression

$$
p_{n}^{(i)}=\frac{1}{\prod_{k=1}^{n-1} c_{k}} \operatorname{det}\left[\begin{array}{ccccc}
c_{1}+i d_{1} & i d_{1} & \cdots & i d_{1} & p_{1} \\
i d_{1} & c_{2}+i d_{2} & \cdots & i d d_{2} & p_{2} \\
\vdots & \vdots & \ddots & \vdots & \vdots \\
i d_{1} & i d_{2} & \cdots & c_{n, 1}+i d_{n} & p_{n} \\
i d_{1} & i d_{2} & \cdots & i d_{n-1} & p_{n}
\end{array}\right] .
$$

Next we subtract the bottom row from the remaining row to obtain

$$
\begin{array}{rl}
p_{n}^{(\dot{)}}= & \frac{1}{\prod_{k=1}^{n-1} c_{k}} \\
& \times \operatorname{det}\left[\begin{array}{cccccc}
c_{1} & \lambda\left(d_{1}-d_{2}\right) & i\left(d_{1}-d_{3}\right) & \cdots & i\left(d_{1}-d_{n}\right. & 1) \\
0 & c_{2} & \lambda\left(d_{2}-d_{3}\right) & \cdots & p_{1}-p_{2} \\
i\left(d_{2}-d_{n}\right. & 1
\end{array}\right)  \tag{2.5}\\
p_{2}-p_{n} \\
0 & 0
\end{array}
$$

Except for the bottom row, we have an upper triangular matrix. To evaluate its determinant in a closed form, we seek Gaussian elimination coefficients to induce zeros into the bottom row: These are functions $x_{1}(\lambda), x_{2}(\lambda), \ldots, x_{n-1}(\lambda)$ such that

$$
\begin{equation*}
i d_{m}-i \sum_{k=1}^{m-1}\left(d_{m}-d_{k}\right) x_{k}+c_{m} x_{m}=0, \quad m=1,2, \ldots, n-1 \tag{2.6}
\end{equation*}
$$

Note that the $\alpha_{m}$ 's do not depend on $n$.

Lemma 1. The solution of (2.6) obeys the three-term recurrence relation

$$
\begin{align*}
& c_{m+1}\left(d_{m}-d_{m-1}\right) \alpha_{m+1} \\
& =\left(c_{m}\left(d_{m+1}-d_{m-1}\right)+\lambda\left(d_{m+1}-d_{m}\right)\left(d_{m}-d_{m} 1\right)\right) \alpha_{m} \\
& \quad-c_{m-1}\left(d_{m+1}-d_{m}\right) \alpha_{m} \quad 1 . \tag{2.7}
\end{align*}
$$

Proof. We set

$$
\begin{align*}
\Phi:= & c_{m+1}\left(d_{m}-d_{m}\right) x_{m+1}-\left\{c_{m}\left(d_{m+1}-d_{m-1}\right)\right. \\
& \left.+\lambda\left(d_{m+1}-d_{m}\right)\left(d_{m}-d_{m-1}\right)\right\} x_{m}-c_{m+1}\left(d_{m+1}-d_{m}\right) x_{m} \quad . \tag{2.8}
\end{align*}
$$

Rearranging (2.6) yields

$$
c_{m} \alpha_{m}=\lambda\left(\sum_{k=1}^{m-1}\left(d_{m}-d_{k}\right) \alpha_{k}-d_{m}\right) .
$$

We replace $c_{1}, x_{l}$ for $l \in\{m-1, m, m+1\}$ in (2.8) by the above expression to obtain

$$
\left.\left.\begin{array}{rl}
\Phi= & i\left\{\left(\begin{array}{ll}
d_{m}-d_{m} & 1
\end{array}\right)\left(\sum_{k-1}^{m}\left(d_{m+1}-d_{k}\right) x_{k}-d_{m+1}\right)\right. \\
& -\left(\begin{array}{ll}
d_{m+1}-d_{m} & 1
\end{array}\right)\left(\sum_{k-1}^{m}\left(d_{m}-d_{k}\right) x_{k}-d_{m}\right) \\
& -\left(d_{m+1}-d_{m}\right)\left(\begin{array}{ll}
\left.\sum_{k=1}^{m}\left(\begin{array}{ll}
d_{m} & 1
\end{array}\right) d_{k}\right) x_{k}-d_{m} & 1
\end{array}\right) \\
& -\left(d_{m+1}-d_{m}\right)\left(d_{m}-d_{m}\right. \\
1
\end{array}\right) x_{m}\right\}=0 .
$$

The proof follows.
Note that, in order that (2.7) defines $\alpha_{m+1}$, it is necessary that $d_{m}-d_{m, 1} \neq 0$. It can be casily seen that this is, in fact, the case: if $d_{m}=d_{m-1}$ then the $m$ th and ( $m-1$ ) st rows of the matrix $\mathbf{D}$ coincide and $\mathbf{D}$ is singular. This is impossible, because $\mathbf{D}$ is a Gram matrix of linearly independent polynomials. An alternative proof is implicit in the statement of the second corollary to Theorem 2.

The three-term recurrence relation (2.7) is accompanied by the initial conditions

$$
\begin{align*}
& \alpha_{1}(\lambda)=-\frac{d_{1}}{c_{1}} \dot{\lambda}  \tag{2.9}\\
& x_{2}(\lambda)=-\frac{d_{2}}{c_{2}} \dot{i}-\frac{d_{1}\left(d_{2}-d_{1}\right)}{c_{1} c_{2}} \dot{\lambda}^{2} \tag{2.10}
\end{align*}
$$

Once the $\alpha_{m}$ 's have been determined by (2.7), (2.9) (2.10), we evaluate the determinant in (2.5) by forming the product of the diagonal terms, except that we must replace $p_{n}$ by the outcome of the elimination procedure in the ( $n, n$ )th entry of the matrix, namely $p_{n}+\sum_{k=1}^{n=1} \alpha_{k}\left(p_{k}-p_{n}\right)$. The result is

$$
\begin{equation*}
p_{n}^{(\lambda)}(x)=\sum_{m=1}^{n-1} \alpha_{m}(i) p_{m}(x)+\left(1-\sum_{m=1}^{n} x_{m}(\lambda)\right) p_{n}(x) . \tag{2.11}
\end{equation*}
$$

Comparing with (2.1), it follows at once that we can identify $r_{m}^{(n)}$ with $\alpha_{m}$ for $m=1,2, \ldots, n-1$. In particular, it is a consequence of our analysis that $r_{m}^{(n)}$ is independent of $n$ for $m=1, \ldots, n-1$. Before we formulate our results in a theorem, we need to take care of the coefficient of $p_{n}$.

The identity (2.6) implies that

$$
\begin{equation*}
\lambda \sum_{k=1}^{m} d_{k} \alpha_{k}=-c_{m} \alpha_{m}-\hat{\lambda} d_{m}+\lambda d_{m} \sum_{k \cdots 1}^{m-1} \alpha_{k} . \tag{2.12}
\end{equation*}
$$

We shift the index by one in the last equation and add $i d_{m} \mid x_{m}$, to both sides to obtain

$$
\begin{equation*}
i \sum_{k}^{m-1} d_{k} \alpha_{k}=-c_{m} \quad 1 \alpha_{m}-i d_{m},+i d_{m} \quad \sum_{k}^{m} x_{1}^{1} \alpha_{k} \tag{2.13}
\end{equation*}
$$

Next, we solve Eqs. (2.12)-(2.13) for $\sum_{k-1}^{m} x_{k}$ and $\sum_{k-1}^{m} d_{k} x_{k}$. This yields

$$
\begin{aligned}
& \sum_{k-1}^{m} x_{k}=1+\frac{c_{m} \alpha_{m}-c_{m} \alpha_{m-1}}{\lambda\left(d_{m}-d_{m} 1\right)} ; \\
& \sum_{k-1}^{m-1} d_{k} x_{k}=\frac{c_{m} d_{m} \quad x_{m}-c_{m} \quad d_{m} \alpha_{m-1}}{\lambda\left(d_{m}-d_{m-1}\right)} .
\end{aligned}
$$

Substitution into (2.11) finally produces the expansion of Sobolevorthogonal polynomials:

Thforfm 2. If $\{d \varphi, d \psi\}$ form a coherent pair then

$$
\begin{equation*}
p_{n}^{(i)}(x)=\sum_{k-1}^{n} \alpha_{k}(i) p_{k}(x)-\frac{c_{n} \alpha_{n}(\lambda)-c_{n} \alpha_{n}(i)}{\lambda\left(d_{n}-d_{n} \quad 1\right)} p_{n}(x), \tag{2.14}
\end{equation*}
$$

where $\alpha_{1}, \alpha_{2}, \ldots, \alpha_{n-1}$ obey the three-term recurrence relation (2.7). Consequently, the coefficients $r_{k}^{(n)}, k=1, \ldots, n-1$, depend only on their subscript.

Corollary. Subject to coherence, it is true that
$p_{n+1}^{(\lambda)}(x)-p_{n}^{(\lambda)}(x)=-\frac{c_{n+1} x_{n+1}(\lambda)-c_{n} x_{n}(\lambda)}{\lambda\left(d_{n+1}-d_{n}\right)}\left(p_{n+1}(x)-p_{n}(x)\right)$.
Proof. We subtract (2.14) from a corresponding expression for $p_{n+1}^{(,)}$. This produces

$$
\begin{align*}
p_{n+1}^{(\lambda)}(x)-p_{n}^{(\lambda)}(x)= & -\frac{c_{n+1} x_{n+1}(\lambda)-c_{n} \alpha_{n}(\lambda)}{\lambda\left(d_{n+1}-d_{n}\right)} p_{n, 1}(x)+\alpha_{n}(\lambda) p_{n}(x) \\
& +\frac{c_{n} \alpha_{n}(\lambda)-c_{n} \alpha_{n-1}(\lambda)}{\lambda\left(d_{n}-d_{n}\right)} p_{n}(x) . \tag{2.16}
\end{align*}
$$

It follows from (2.6) that

$$
\frac{c_{n+1} x_{n+1}(i)-c_{n} x_{n}(i)}{d_{n+1}-d_{n}}=i x_{n}(i)+\frac{c_{n} \alpha_{n}(i)-c_{n-1} x_{n-1}(i)}{d_{n}-d_{n-1}}
$$

and substitution in (2.16) furnishes the required expression.

The definition of coherence may seem at first sight rather strange and difficult to verify. Fortunately, we are able to show that it is equivalent to a condition that is far less technical.

Theorem 3. The pair $\{d \varphi, d \psi\}$ is coherent if and only if there exist nonzero constants $C_{1}, C_{2}, \ldots$ such that

$$
\begin{equation*}
q_{n}(x)=C_{n+1} p_{n+1}^{\prime}(x)-C_{n} p_{n}^{\prime}(x), \quad n=1,2, \ldots \tag{2.17}
\end{equation*}
$$

Proof. Let us first assume that $\{d \varphi, d \psi\}$ is coherent. Hence there exist non-zero $C_{1}, C_{2}, \ldots$ such that

$$
\int_{\alpha_{c}}^{x} p_{m}^{\prime}(x) p_{k}^{\prime}(x) d \psi(x)=\frac{d_{\min \{m, k\}}}{C_{m} C_{k}}, \quad k, m=1,2, \ldots
$$

and it follows at once that

$$
\int_{0}^{x} p_{m}^{\prime}(x)\left(C_{n+1} p_{n+1}^{\prime}(x)-C_{n} p_{n}^{\prime}(x)\right) d \psi(x)=0, \quad m=1,2, \ldots, n .
$$

But $\left\{p_{1}^{\prime}, p_{2}^{\prime}, \ldots, p_{n}^{\prime}\right\}$ spans all $(n-1)$ th degree polynomials, hence, (2.17) is true.

The opposite statement follows just as readily, be reversing our argument: assuming that (2.17) holds, we have

$$
0=\int_{-x}^{\infty} p_{m}(x) q_{n}(x) d \psi(x)=\int_{x}^{x} p_{m}^{\prime}(x)\left(C_{n+1} p_{n+1}^{\prime}(x)-C_{n} p_{n}^{\prime}(x)\right) d \psi(x)
$$

for all $m=1,2, \ldots, n$, therefore,

$$
d_{m . n+1}=\frac{C_{n}}{C_{n+1}} d_{m . n}, \quad m=1,2, \ldots, n .
$$

It follows that $C_{n} C_{m} d_{n, m}$ is independent of $n$ for all $m \leqslant n$ and depends only on $m=\min \{m, n\}$ precisely the definition of coherence.

Corollary. Subject to coherence and assuming, without loss of generality, that $C_{n} \equiv 1$, it is true that

$$
\begin{equation*}
d_{n+1}-d_{n}=e_{n}>0, \quad n=0,1, \ldots \tag{2.18}
\end{equation*}
$$

In particular, $d_{n+1}-d_{n}$ never vanishes.

Proof. Subtracting

$$
d_{n}=\int_{x}^{t} p_{n}^{\prime}(x) p_{n, 1}^{\prime}(x) d \psi(x)
$$

from

$$
d_{n+1}=\int_{x}^{x} p_{n+1}^{\prime}(x) d \psi(x)
$$

results in

$$
\begin{aligned}
d_{n+1}-d_{n} & =\int_{x}^{x} p_{n+1}^{\prime}(x)\left(p_{n+1}^{\prime}(x)-p_{n}^{\prime}(x)\right) d \psi(x) \\
& =\int_{-x}^{x} p_{n+1}^{\prime}(x) q_{n}(x) d \psi(x)=\int_{x}^{e} q_{n}^{2}(x) d \psi(x)=e_{n}
\end{aligned}
$$

Note that we have exploited the identity

$$
\int_{-x}^{x} p_{n}^{\prime}(x) q_{n}(x) d \psi(x)=0
$$

in the derivation of the last expression.
Corollary. Subject to coherence and assuming, without loss of generality, that $C_{n} \equiv 1$, it is true that

$$
\begin{equation*}
\frac{d}{d x}\left(p_{n+1}^{(\lambda)}(x)-p_{n}^{(i)}(x)\right)=-\frac{c_{n+1} x_{n+1}(i)-c_{n} x_{n}(\lambda)}{\lambda\left(d_{n+1}-d_{n}\right)} q_{n}(x) \tag{2.19}
\end{equation*}
$$

Proof. A straightforward juxtaposition of Theorems 2 and 3.
Before we conclude this section it is worthwhile to note that the threeterm recurrence relation (2.7) can be rewritten in a simplified form involving $e_{n}=d_{n+1}-d_{n}$,

$$
\begin{align*}
& c_{m+1} e_{m, 1} x_{m+1}(i) \\
& \quad=\left(c_{m}\left(e_{m}+e_{m} \quad 1\right)+i e_{m \quad 1} e_{m}\right) x_{m}(\lambda)-c_{m} \quad 1 e_{m} x_{m} \quad 1(i) . \tag{2.20}
\end{align*}
$$

## 3. Coherent Pairs and Classical Orthogonal Polynomials

Given two Borel measures $d \varphi$ and $d \psi$, we say that $d \psi$ is a companion of $d \varphi$ if $\{d \varphi, d \psi\}$ form a coherent pair.

In the present section we assume that $d \varphi$ is a measure that produces one of the classical orthogonal polynomials-Jacobi, Laguerre, or Hermite-and seek its companions. According to a theorem of Hahn [11], classical orthogonal polynomials are precisely all the orthogonal polynomials whose derivatives are also orthogonal with respect to some Borel measure dv. Let us denote the monic orthogonal polynomials with respect to $d v$ by $\pi_{0}, \pi_{1}, \ldots$ Thus,

$$
\pi_{n}(x)=\frac{1}{n+1} p_{n+1}^{\prime}(x), \quad n=0,1, \ldots
$$

where we stipulate, without loss of generality, that the $p_{n}$ 's are monic. The main tool of our analysis is the identity (2.17), which expresses the $q_{n}$ 's, subject to coherence, in terms of the $\pi_{n}$ 's.

Suppose that the $\pi_{n}$ 's obey the recurrence relation

$$
\begin{equation*}
\pi_{n+1}(x)=\left(x-\alpha_{n}\right) \pi_{n}(x)-\beta_{n} \pi_{n, 1}(x) \tag{3.1}
\end{equation*}
$$

We let

$$
\begin{align*}
& q_{0}(x): \equiv 1 \\
& q_{n}(x):=\pi_{n}(x)-\sigma_{n} \pi_{n} \quad(x), \quad n=1,2, \ldots \tag{3.2}
\end{align*}
$$

(hence the $q_{n}$ 's are quasi-orthogonal with respect to $d v$ [7]) and seek real constants $\sigma_{1}, \sigma_{2}, \ldots \neq 0$ such that $\left\{q_{n}\right\}_{n=0}^{\infty}$ is an orthogonal polynomial system. According to the Favard theorem [7], this is the case if and only if the $q_{n}$ 's obey a three-term recurrence relation, which we write as

$$
\begin{equation*}
q_{n+1}(x)=\left(x-\gamma_{n}\right) q_{n}(x)-\delta_{n} q_{n} \quad 1(x) \tag{3.3}
\end{equation*}
$$

Substitution of (3.2) into (3.3) yields

$$
\begin{aligned}
\pi_{n+1}(x)= & \left(x+\sigma_{n+1}-\gamma_{n}\right) \pi_{n}(x) \\
& -\left(\sigma_{n} x-\sigma_{n} \hat{\gamma}_{n}+\delta_{n}\right) \pi_{n} \quad 1(x)+\sigma_{n} \quad{ }_{1} \delta_{n} \pi_{n-2}(x) .
\end{aligned}
$$

We now exploit (3.1) to replace $\pi_{n+1}$ and $\pi_{n}{ }_{2}$ in the last formula. This gives

$$
\begin{align*}
\left(x_{n}+\sigma_{n+1}-\gamma_{n}-\frac{\sigma_{n-1} \delta_{n}}{\beta_{n} 1}\right) \pi_{n}(x) & =\left(\left(\delta_{n}-\beta_{n}-\sigma_{n} \gamma_{n}+\frac{\sigma_{n} \delta_{n} \alpha_{n-1}}{\beta_{n 1}}\right)\right. \\
& \left.+\left(\sigma_{n}-\frac{\sigma_{n-1} \delta_{n}}{\beta_{n} 1}\right) x\right) \pi_{n} \quad(x) \tag{3.4}
\end{align*}
$$

Let us examine (3.4). Since $\pi_{n-1}$ and $\pi_{n}$ cannot share zeros, both sides of the equation must necessarily vanish. Thus, we obtain

$$
\begin{align*}
\alpha_{n}+\sigma_{n+1}-\hat{\gamma}_{n}-\frac{\sigma_{n-1} \delta_{n}}{\beta_{n} 1} & =0  \tag{3.5}\\
\beta_{n}+\sigma_{n} \gamma_{n}-\delta_{n}-\frac{\sigma_{n-1} \delta_{n} \alpha_{n-1}}{\beta_{n} 1} & =0  \tag{3.6}\\
\sigma_{n}-\frac{\sigma_{n-1} \delta_{n}}{\beta_{n-1}} & =0 \tag{3.7}
\end{align*}
$$

The identity (3.7) yields

$$
\delta_{n}=\frac{\sigma_{n}}{\sigma_{n} \quad} \beta_{n}
$$

(recall that the $\sigma_{n}$ 's do not vanish!) and substitution in (3.5)-(3.6) results in

$$
\begin{gather*}
x_{n}+\sigma_{n+1}-i_{n}-\sigma_{n}=0,  \tag{3.8}\\
\frac{\beta_{n}}{\sigma_{n}+}-\frac{\beta_{n}}{\sigma_{n}}+x_{n-1}=\gamma_{n} . \tag{3.9}
\end{gather*}
$$

Substitution of (3.9) into (3.8) gives

$$
\sigma_{n+1}+x_{n}+\frac{\beta_{n}}{\sigma_{n}}=\sigma_{n}+x_{n} \quad 1+\frac{\beta_{n-1}}{\sigma_{n} \quad .}
$$

Consequently, the quantity $\sigma_{n+1}+x_{n}+\beta_{n} / \sigma_{n}$ is independent of $n$ and there exists a real number $\xi$ such that

$$
\begin{equation*}
\sigma_{n+1}+\alpha_{n}+\frac{\beta_{n}}{\sigma_{n}}=\xi, \quad n=0,1, \ldots \tag{3.10}
\end{equation*}
$$

We now set

$$
\begin{aligned}
& A_{0}: \equiv 1, \\
& A_{n}:=\sigma_{1} \sigma_{2} \cdots \sigma_{n}, \quad n=1,2, \ldots .
\end{aligned}
$$

Thus, $\sigma_{n}=A_{n} / A_{n-1}$ and substitution into (3.10) affirms that each $A_{n}$ is a monic $n$th degree polynomial in $\xi$ that obeys the recurrence relation

$$
\begin{equation*}
A_{n+1}(\xi)=\left(\xi-\alpha_{n}\right) A_{n}(\xi)-\beta_{n} A_{n+1}(\xi) . \tag{3.11}
\end{equation*}
$$

Note that the recurrence relations (3.1) and (3.11) are identical, although, of course, they are subject to different initial conditions. The general solution of (3.11) can be expressed as $\left\{a \pi_{n}(x)+(1-a) \pi_{n}^{(1)}(x)\right\}_{n=0}$, where the $\pi_{n}^{(1) ’ s}$ are the numerator polynomials corresponding to the measure do [7]. It now follows from (3.3) that, for all $n=1,2, \ldots$,

$$
\begin{equation*}
q_{n}(x)=\frac{1}{A_{n-1}(\zeta)}\left(A_{n-1}(\zeta) \pi_{n}(x)-A_{n}(\check{\xi}) \pi_{n} \quad(x)\right) . \tag{3.12}
\end{equation*}
$$

Polynomials of this form were already investigated in $[9,12,15,16,21$, 22], mainly because of their connection with Christoffel weights of certain quadrature formulae. In particular, Maroni [21] proved that, subject to $\xi$ being outside the (open) essential support of $d v$ and to $d v$ corresponding to one of the classical orthogonal polynomials, they are orthogonal with respect to the measure

$$
\begin{equation*}
(1-c) \delta(x-\xi) d x+c \frac{d v(x)}{|x-\xi|}, \tag{3.13}
\end{equation*}
$$

where $0<c \leqslant 1$.
In the case of a Jacobi measure,

$$
d \varphi(x)=(1-x)^{x}(1+x)^{\beta} d x, \quad x \in(-1,1),
$$

where $\alpha, \beta>-1$, it is well known that

$$
d v(x)=(1-x)^{x+1}(1+x)^{1+\beta} d x, \quad x \in(-1,1)
$$

[23]. Thus, letting $\xi=-1$ and $c=1$ in (3.13), we obtain

$$
d \psi(x)=(1-x)^{1+x}(1-x)^{\beta} d x, \quad x \in(-1,1)
$$

as a particular example of a companion of $d \varphi$.
Likewise, the Laguerre measure

$$
d \varphi(x)=x^{x} e^{-x} d x, \quad x>0
$$

where $x>-1$, yields

$$
d v(x)=x^{x+1} e^{x} d x, \quad x>0
$$

[23]. Thus, an example of a measure that results in a coherent pair follows when we choose $\zeta=0$ and $c=1$ in (3.13): in that case $d \psi(x) \equiv d \varphi(x)$.
Finally, it is easy to see that if

$$
d \varphi(x)=e^{x^{2}} d x, \quad x \in(-x, x)
$$

the Hermite measure, there exists no companion, since the support of $d \varphi$ (and hence of $d v$ ) is the whole real line and we cannot chose a real number $\xi$ in (3.13).

## 4. Symmetricaliy Coherent Pairs

If both measures $d \varphi$ and $d \psi$ are symmetric (i.c., invariant under the transformation $x \mapsto-x$ ) then $p_{n}^{(\lambda)}, p_{n}$, and $q_{n}$ are of the same parity as $n$. Therefore, expanding $p_{n}^{(i)}$ in $p_{m}$ 's, only terms that share the parity of $n$ are present. Consequently, expansion coefficients depend on parity and the pair $\{d \varphi, d \psi\}$ cannot be coherent. (Note the lack of symmetry of the companions $(1-x)^{x+1}(1+x)^{x} d x,(1-x)^{x}(1+x)^{x+1} d x$ found above for the symmetric Jacobi measure $(1-x)^{x}(1+x)^{x} d x, x>-1$.) Fortunately, a relatively minor generalization of coherence caters for this situation.

Given symmetric $d \varphi$ and $d \psi$, we say that $\{d \varphi, d \psi\}$ is symmetrically coherent if

$$
d_{k, m}= \begin{cases}C_{k} C_{m} d_{\min \{k, m\}}: & k \text { and } m \text { are of the same parity } \\ 0: & \text { otherwise. }\end{cases}
$$

Moreover, a measure $d \psi$ is termed a symmetric companion of $d \varphi$ if the pair $\{d \varphi, d \psi\}$ is symmetrically coherent. All the results of Section 2 translate to this framework, with obvious amendments:

Theorem 4. (a) The pair $\{d \varphi, d \psi\}$ of symmetric measures is symmetrically coherent if and only if there exist non-zero constants $C_{1}, C_{2}, \ldots$ such that

$$
q_{n}(x)=C_{n+1} p_{n+1}^{\prime}(x)-C_{n} \quad, p_{n}^{\prime} \quad, 1(x) .
$$

(b) Subject to symmetric coherence and assuming that, without loss of generality, $C_{n} \equiv 1$, it is true that

$$
p_{n}^{(\lambda)}(x)=\sum_{k}^{[n ; 2]-1} \alpha_{n-2 k}(\lambda) p_{n-2 k}(x)-\frac{c_{n} \alpha_{n}(i)-c_{n}{ }_{2} \alpha_{n}{ }_{2}(\dot{\lambda})}{\hat{\lambda}\left(d_{n}-d_{n}{ }_{2}\right)} p_{n}(x)
$$

where the $\alpha_{k}$ 's obey the three-term recurrence relation

$$
c_{m+2} e_{m} \quad{ }_{2} \alpha_{m+2}(\hat{\lambda})=\left(c_{m}\left(e_{m}+e_{m-2}\right)+\hat{\lambda} e_{m-2} e_{m}\right) \alpha_{m}(i)-c_{m} \quad 2 e_{m} \alpha_{m} \quad 2(\lambda)
$$

(c) Subject to the same conditions, it is true that

$$
p_{n+1}^{(\lambda)}(x)-p_{n}^{(\lambda)}(x)=-\frac{c_{n+1} \alpha_{n+1}(\lambda)-c_{n+1} \alpha_{n \cdot 1}(\lambda)}{\lambda\left(d_{n+1}-d_{n-1}\right)}\left(p_{n+1}(x)-p_{n-1}(x)\right)
$$

and

$$
\frac{d}{d x}\left(p_{n+1}^{(i)}(x)-p_{n}^{(i)},(x)\right)=-\frac{c_{n+1} x_{n+1}(\lambda)-c_{n}, x_{n}, i(i)}{\dot{\lambda}\left(d_{n+1}-d_{n}, 1\right)} q_{n}(x) .
$$

We need symmetric measures for symmetric coherence and our first example is the Hermite measure $d \varphi(x)=e{ }^{r^{2}} d x,-\infty<x<x$, that already has been debated in Section 3 in the context of coherent pairs. Thus, we have

$$
H_{n+1}(x)=2 x H_{n}(x)-2 n H_{n-1}(x)
$$

and the polynomials $q_{n}$, being themselves orthogonal with respect to a symmetric measure, obey a three-term recurrence relation of the form

$$
\begin{equation*}
q_{n+1}(x)=a_{n} x q_{n}(x)-f_{n} q_{n} \quad 1(x) . \tag{4.1}
\end{equation*}
$$

Since $q_{n}=C_{n+1} H_{n+1}^{\prime}-C_{n}{ }_{1} H_{n}^{\prime} \quad$, and $H_{n}^{\prime}=2 n H_{n, 1}$, substitution into (4.1) yields

$$
\begin{aligned}
(n+2) C_{n+2} H_{n+1}-n C_{n} H_{n,}= & a_{n} x\left((n+1) C_{n+1} H_{n}-(n-1) C_{n}, H_{n-2}\right) \\
& -f_{n}\left(n C_{n} H_{n},(n-2) C_{n}, H_{n} \quad 3\right) .
\end{aligned}
$$

Replacing $H_{n+1}$ with $2 x H_{n}-2 n H_{n-1}$ and $H_{n}$, with $\left(x H_{n-2}-\frac{1}{2} H_{n} \quad\right.$ ) ( $n-2$ ) leads to

$$
\begin{aligned}
& x\left(2(n+2) C_{n+2}-(n+1) a_{n} C_{n+1}\right) H_{n} \\
& \quad+\left(-n C_{n}+n f_{n} C_{n}+\frac{1}{2} f_{n} C_{n-2}-2 n(n+1) C_{n+2}\right) H_{n} \quad \\
& \quad+x\left((n-1) a_{n} C_{n-1}-f_{n} C_{n-2}\right) H_{n}=0 .
\end{aligned}
$$

Next, we substitute $\left(x H_{n} \quad 1-\frac{1}{2} H_{n}\right) /(n-1)$ instead of $H_{n} \quad 2$. This yields

$$
A_{n}^{*} x H_{n}(x)+\left(B_{n}^{*}+C_{n}^{*} x^{2}\right) H_{n} \quad(x)=0,
$$

where

$$
\begin{aligned}
& A_{n}^{*}=2(n+2) C_{n+2}-(n+1) a_{n} C_{n+1}-\frac{1}{2} a_{n} C_{n}+\frac{1}{2} \frac{1}{n-1} f_{n} C_{n} \quad \\
& B_{n}^{*}=-n C_{n}+n f_{n} C_{n}+\frac{1}{2} f_{n} C_{n} \quad 2-2 n(n+2) C_{n+2} \\
& C_{n}^{*}=a_{n} C_{n} \quad 1-\frac{1}{n-1} f_{n} C_{n} .
\end{aligned}
$$

As in Section 3, it follows that $A_{n}^{*}=B_{n}^{*}=C_{n}^{*}=0$, since $H_{n}$ and $H_{n}$, cannot share zeros. We obtain

$$
\begin{aligned}
& a_{n}=\frac{n}{n-1} \frac{C_{n}}{C_{n-1}} \frac{2(n+2) C_{n+2}+C_{n}}{n C_{n}+\frac{1}{2} C_{n}}, \\
& f_{n}=n \frac{2(n+2) C_{n+2}+C_{n}}{n C_{n}+\frac{1}{2} C_{n 2}}, \quad n=2,3, \ldots,
\end{aligned}
$$

where

$$
\rho_{n}:=(n+1) \frac{C_{n+1}}{C_{n}}
$$

obeys the non-linear recurrence

$$
\begin{equation*}
(n-1)\left(2 \rho_{n} \quad 1+1\right) \rho_{n+1}=\rho_{n} . \tag{4.2}
\end{equation*}
$$

It is easy to see that any initial conditions $\rho_{1}, \rho_{2}>0$ produce in (4.2) a positive solution sequence. In that case $a_{n}, f_{n}>0$ and the measure that generates $\left\{q_{n}\right\}$ is positive definite. Thus, we have an example of a measure that has an infinite number of symmetric companions (and, as we have demonstrated in Section 3, no companions, whether symmetric or not).

Our next example of a symmetric measure with a symmetric companion is the Gegenbauer measure $d \varphi(x)=\left(1-x^{2}\right)^{x}{ }^{12}, x \in(-1,1)$, where $v>0$. Thus, $p_{n}=C_{n}^{n}$, the Gegenbauer polynomials [23]. Special cases include $r=\frac{1}{2}$, the Legendre measure, and $v=1$, the Chebyshev measure of the second kind. We do not try to find all the symmetric companions-a single example will suffice. Since

$$
\frac{d}{d x}\left\{C_{n-1}^{v}(x)-C_{n}^{v}(x)\right\}=2(n+v) C_{n}^{\prime}(x)
$$

[23], it follows at once that the Gegenbauer measure is a symmetric companion of itself.

This construction fails when $v=0$, since Gegenbauer polynomials are not defined. This is an important special case, since it corresponds to the Chebyshev measure of the first kind. Fortunately, this measure is a companion of itself for $p_{n}:-T_{n}, C_{n}:=1 / n$, as can be seen at once from

$$
\frac{d}{d x}\left\{\frac{T_{n+1}}{n+1}-\frac{T_{n} 1}{n-1}\right\}=U_{n}-U_{n} \quad=2 T_{n}
$$

Note that the framework of Section 3 can be extended to symmetrically coherent pairs, thereby characterizing all the symmetric companions of Gegenbauer and Hermite measures.

## 5. Orthogonality Relations of the Expansion Coefficients

We have seen that, $\{d \varphi, d \psi\}$ being a coherent pair, the expansion coefficients in (2.1), except for the last, obey the recurrence relation (2.20). In the present section we investigate some implications of this relation. Note that we replace $\lambda$ with $x$, to emphasize that it is now the main variable, rather than a parameter.

Theorem 5. Let

$$
R_{n}(x):=\frac{x_{n+1}(x)}{x_{1}(x)}=-\frac{c_{1}}{d_{1}} \frac{x_{n+1}(x)}{x}, \quad n=0,1, \ldots
$$

Then the set $\left\{R_{n}\right\}_{n=0}^{x}$ is orthogonal with respect to some Borel measure.
Proof. We have from (2.9)-(2.10) and from (2.18) that

$$
\begin{equation*}
R_{0}(x) \equiv 1, \quad R_{1}(x)=\frac{c_{1} d_{2}}{c_{2} d_{1}}+\frac{e_{1}}{c_{2}} x \tag{5.1}
\end{equation*}
$$

Moreover, the identity (2.20) is "translated" into

$$
\begin{align*}
& c_{n+2} e_{n} R_{n+1}(x) \\
& \quad=\left(e_{n} e_{n+1} x+c_{n+1}\left(e_{n+1}+e_{n}\right)\right) R_{n}(x)-c_{n} e_{n+1} R_{n} \quad 1(x) \tag{5.2}
\end{align*}
$$

The coefficients $c_{m}$ and $e_{m}$ are positive for all $m=0,1, \ldots$. We now invoke the Favard theorem [7] to deduce that there exists a Borel measure $d x$ such that

$$
\int_{x}^{x} R_{m}(x) R_{n}(x) d \chi(x)=0, \quad m \neq n .
$$

The general connection between the measures $d \varphi, d \psi$, and $d \chi$ has not been clarified as yet. However, several special cases are amenable to analysis. It is convenient, first, to rewrite (5.1) (5.2) in terms of monic polynomials. These are $\hat{R}_{n}$ such that

$$
\begin{align*}
\hat{R}_{0}(x) & \equiv 1, \quad \hat{R}_{1}(x)=c_{1}\left(\frac{1}{e_{0}}+\frac{1}{e_{1}}\right)+x,  \tag{5.3}\\
\hat{R}_{n+1}(x) & =\left\{x+c_{n+1}\left(\frac{1}{e_{n}}+\frac{1}{e_{n+1}}\right)\right\} \hat{R}_{n}(x)-\frac{c_{n} c_{n-1}}{e_{n}^{2}} \hat{R}_{n-1}(x)
\end{align*}
$$

this can be readily verified, e.g., by using formulae from [7].

We have proved in Section 3 that the Laguerre measure is a companion of itself. We have $p_{n}=q_{n}=L_{n}^{(\alpha)}, \alpha>-1$, and

$$
c_{n}=e_{n}=\frac{\Gamma(n+\alpha+1)}{n!}, \quad n=0,1, \ldots
$$

[23]. Writing $R_{n}^{*}(x):=R_{n}(2 x-2)$, we act on (5.2) to obtain

$$
\begin{aligned}
(n+1)(n+2+x) R_{n+1}^{*}(x)= & (n+2)(2(n+1) x+x) R_{n}^{*}(x) \\
& -(n+1)(n+2) R_{n}^{*} \quad(x) .
\end{aligned}
$$

They can be converted to their monic version:

$$
\begin{equation*}
\hat{R}_{n+1}^{*}(x)=\left(x+\frac{x}{2(n+1)}\right) \hat{R}_{n}^{*}(x)-\frac{n+x-1}{4(n+1)} \hat{R}_{n}^{*} \quad(x) \tag{5.4}
\end{equation*}
$$

We compare (5.4) with the recurrence formula for the monic Pollaczek polynomials

$$
\hat{P}_{n+1}^{i}(x)=\left(x+\frac{b}{n+i+a}\right) \hat{P}_{n}^{i}(x)-\frac{n(n+2 i-1)}{4(n+i+a-1)(n+i+a)} \hat{P}_{n}^{i} \quad,(x)
$$

where $a, b, i \in\{$ and $a+i>0$ [7]. It readily follows that the formulae coincide for the choice $a=-x_{i}^{\prime} 2, b=x_{i} 2$, and $\lambda=1+x_{i}$. Consequently,

$$
R_{n}(x)=\frac{(n+1)!}{(2+x)_{n}} P_{n}^{1+x: 2}\left(1+\frac{1}{2} x ;-\frac{x}{2}, \frac{\alpha}{2}\right) .
$$

Orthogonality properties of Pollaczek polynomials are known when $a \geqslant|b|$ [7]. This corresponds to the case $\alpha \in(-1,0]$ and we have

$$
\begin{aligned}
d \chi(2 x-2)= & \left(1-x^{2}\right)^{(1 \cdot 2)(1+x)} \exp \left(x\left(\cos ^{1} x-\frac{\pi}{2}\right)\left(\frac{1-x}{1+x}\right)^{1: 2}\right) \\
& \times\left|I\left(1+\frac{x}{2}\left(1+i\left(\frac{1-x}{1+x}\right)^{12}\right)\right)\right|^{2} d x, \quad x \in(-1,1)
\end{aligned}
$$

The support of $d \chi$ is the interval ( $-4,0$ ). If $\alpha=0$ then $d \chi$ reduces to a shifted Chebyshev measure of the second kind. Note that the underlying measure has been identified for other values of $a$ and $b$ in [2].

The next object of our attention is the Jacobi measure. We proved in Section 3 that a coherent choice is

$$
\begin{aligned}
& p_{n}=(-1)^{n} \quad \frac{(\alpha+\beta+2)_{n} 1}{(\alpha+2)_{n} 1} P_{n}^{(x, \beta)} . \\
& q_{n}=\frac{(-1)^{n}}{2} \frac{(\alpha+\beta+2)_{n}}{(\alpha+2)_{n}}(\alpha+\beta+2 n+2) P_{n}^{(\alpha+1, \beta)} .
\end{aligned}
$$

We now exploit the identity

$$
\begin{aligned}
\int_{1}^{1} & (1-x)^{x}(1+x)^{\beta}\left(P_{n}^{(x, \beta)}(x)\right)^{2} d x \\
& =\frac{2^{\alpha+\beta+1} \Gamma(1+\alpha) \Gamma(1+\beta)}{\Gamma(1+\alpha+\beta)} \frac{(1+\alpha)_{n}(1+\beta)_{n}}{n!(1+\alpha+\beta)_{n}(1+\alpha+\beta+2 n)}
\end{aligned}
$$

Setting

$$
C^{(x, \beta)}:=\frac{2^{\alpha+\beta+1} \Gamma(1+\alpha) \Gamma(1+\beta)}{\Gamma(1+\alpha+\beta)}
$$

we obtain

$$
\begin{aligned}
& c_{n}=C^{(\alpha, \beta)}\left(\frac{1+\alpha}{1+\alpha+\beta}\right)^{2} \frac{(1+\beta)_{n}(1+\alpha+\beta)_{n}}{n!(1+\alpha)_{n}(1+\alpha+\beta+2 n)} \\
& e_{n}=\frac{C^{(\alpha+1, \beta)}}{4} \frac{(1+\beta)_{n}(2+\alpha+\beta)_{n}}{n!(2+\alpha)_{n}}
\end{aligned}
$$

and (5.3) gives

$$
\begin{equation*}
\hat{R}_{n+1}(x)=\left(x+a_{n}\right) \hat{R}_{n}(x)-b_{n} \hat{R}_{n-1}(x), \tag{5.5}
\end{equation*}
$$

where

$$
\begin{aligned}
& a_{n}=\frac{\left(3+\alpha+\beta+2 n+\sqrt{(1+\alpha)^{2}-\beta^{2}}\right)\left(3+\alpha+\beta+2 n-\sqrt{(1+\alpha)^{2}-\beta^{2}}\right)}{(1+n)(2+\alpha+\beta+n)(3+\alpha+\beta+2 n)} \\
& b_{n}=4 \frac{(1+\alpha+n)(1+\beta+n)}{(1+n)(1+\alpha+\beta+n)(1+\alpha+\beta+2 n)(3+\alpha+\beta+2 n)}
\end{aligned}
$$

Some combinations of $\alpha$ and $\beta$ yield simplified recurrences (5.5). For example, letting $\beta=0$ produces

$$
\hat{R}_{n+1}(x)=\left(x+\frac{2}{n+v+1}\right) \hat{R}_{n}(x)-\frac{1}{(n+v)(n+v+1)} \hat{R}_{n} \quad(x)
$$

where $v:=\frac{1}{2}(1+\alpha)$. The underlying measure $d_{\chi}$ has not been identified.
Analysis of symmetrically coherent measures is similar to Theorem 5, except that now we have two different three-term recurrences, one for "even" polynomials $E_{n}$ (i.e., those that appear in the expansion of $p_{2 m}^{(i)}$ ) and one for "odd" polynomials $O_{n}$. Our last example concerns the Gegenbauer measures. Since

$$
\int_{-1}^{1}\left(1-x^{2}\right)^{v} \quad 1 / 2\left[C_{n}^{v}(x)\right]^{2} d x=\frac{\Gamma\left(\frac{1}{2}\right) \Gamma\left(v+\frac{1}{2}\right)}{\Gamma(v)} \frac{(2 v)_{n}}{n!(n+v)}
$$

[23], simple calculation leads to the monic recurrences

$$
\begin{aligned}
\hat{E}_{n+1}= & \left\{x+\frac{2 v^{2}+(4 n+5) v+(2 n+1)(2 n+3)}{8(n+1)(n+v+1)(2 n+v+1)(2 n+v+3)}\right\} \hat{E}_{n} \\
& -\frac{(2 n+1)(2 n+2 v+1)}{64(n+1)(n+v)(2 n+v)(2 n+v+1)^{2}(2 n+v+2)} \hat{E}_{n}
\end{aligned}
$$

and

$$
\begin{aligned}
\hat{O}_{n+1}= & \left\{x+\frac{2 v^{2}+(4 n+3) v+4 n(n+1)}{2(2 n+1)(2 n+v)(2 n+v+2)(2 n+2 v+1)}\right\} \hat{O}_{n} \\
& -\frac{n(n+v)}{4(2 n+1)(2 n+v-1)(2 n+v)^{2}(2 n+v+1)(2 n+2 v-1)} \hat{O}_{n}
\end{aligned}
$$

They remain true for the Chebysher measure of the first kind, i.e., when $v=0$.
A very special case is the Legendre measure, which is obtained for $v=\frac{1}{2}$. In that case we have

$$
\begin{align*}
\hat{E}_{n+1}= & \left\{x+\frac{2}{(4 n+3)(4 n+7)}\right\} \hat{E}_{n} \\
& -\frac{1}{(4 n+1)(4 n+3)^{2}(4 n+5)} \hat{E}_{n-1} ;  \tag{5.6}\\
\hat{O}_{n+1}= & \left\{x+\frac{2}{(4 n+1)(4 n+5)}\right\} \hat{O}_{n} \\
& -\frac{1}{(4 n-1)^{2}(4 n+1)^{2}(4 n+3)} \hat{O}_{n+1} . \tag{5.7}
\end{align*}
$$

To identify $d \chi^{(E)}$ and $d \chi^{(0)}$, the "even" and "odd" measures in the Legendre case, we recall for future reference that the modified Lommel measure has a discrete spectrum, with jumps of $1 / j_{r-1, k}^{2}$ at $\pm 1 / j_{v-1, k}, k=1,2, \ldots$, where $j_{\kappa, k}$ is the $k$ th zero of the Bessel function $J_{\kappa}$ and $\nu>1$. The underlying monic orthogonal polynomials posssess the three-term recurrence relation

$$
\begin{equation*}
\hat{h}_{n+1, v}(x)=x \hat{h}_{n, v}(x)-\frac{1}{4(n+v-1)(n+v)} \hat{h}_{n, 1 . v}(x) \tag{5.8}
\end{equation*}
$$

[7].
Let $d \mu$ be a symmetric Borel measure that generates monic orthogonal polynomials $\left\{s_{n}\right\}$ with the three-term recurrence relation

$$
\begin{equation*}
s_{n+1}(x)=x s_{n}(x)-i_{n} s_{n \cdot 1}(x) \tag{5.9}
\end{equation*}
$$

Since $s_{n}$ retains the parity of $n, t_{n}(x):=s_{2 n+1}(\sqrt{x}) / \sqrt{x}$ is a polynomial and it is well known that it is orthogonal with respect to the measure $\sqrt{x} d \mu(\sqrt{x})$, supported by $x \in(0, x)$ [7]. It is quite easy to prove that the $t_{n}$ 's obey the recurrence relation

$$
\begin{equation*}
t_{n+1}(x)=\left(x-i_{2 n+1}-i_{2 n+2}\right) t_{n}(x)-i_{2 n} i_{2 n+1} t_{n} \quad 1(x) . \tag{5.10}
\end{equation*}
$$

We map $x \mapsto-x$ in (5.6). It is now straightforward to verify that (5.6) and (5.10) coincide for the choice

$$
i_{n}=\frac{1}{4(n+v-1)(n+v)}, \quad v=\frac{1}{2} .
$$

Thus, exploiting the connection between (5.9) and (5.10), we deduce that $d \chi^{(t)}$ is a "one-sided" modified Lommel measure. Likewise, $v=\frac{3}{2}$ recovers the recurrence relation for $\hat{O}_{n}$. But

$$
J_{1: 2}(z)=\left(\frac{2}{\pi z}\right)^{1,2} \cos z, \quad J_{1: 2}(z)=\left(\frac{2}{\pi z}\right)^{12} \sin z,
$$

and it transpires that $d \chi^{(E)}$ is an atomic measure with jumps of $1 / k^{4}$ at $-1 /\left(\pi^{2} k^{2}\right), k=1,2, \ldots$ whereas $d \chi^{(0)}$ is an atomic measure with jumps of $1 /\left(k+\frac{1}{2}\right)^{4}$ at $-1 /\left(\pi^{2}\left(k+\frac{1}{2}\right)^{2}\right), k=1,2, \ldots$.

## 6. Evallation of Expansion Coefficients

Orthogonal polynomials can be evaluated very fast and robustly by using their three-term recurrence relations. This is of major importance in approximating the coefficients of expansions (generalized Fourier coefficients) by quadrature. We are denied the comfort of a three-term recurrence relation in the case of Sobolev-orthogonal polynomials. However, if $\{d \varphi, d \psi\}$ form a coherent or a symmetrically coherent pair, calculation of Sobolev-orthogonal polynomials and of Sobolev-Fouricr coefficients can be accomplished efficiently. In the present section we present an algorithm for that purpose. Another technique, as well as a discussion of few examples and approximation-theoretical aspects, appears in [14].

Any $f \in W_{2}^{1}[(-\infty, \infty), d \varphi, d \psi]$ can be expanded in Sobolev-orthogonal polynomials,

$$
f \sim \sum_{n=0}^{\infty} \frac{\hat{f}_{n}(\lambda)}{\hat{p}_{n}^{(\lambda)}} p_{n}^{(i)},
$$

where

$$
\begin{aligned}
\hat{f}_{n}(\lambda) & =\left\langle f, p_{n}^{(\lambda)}\right\rangle_{i} ; \\
\hat{p}_{n}^{(\lambda)} & =\left\langle p_{n}^{(\lambda)}, p_{n}^{(\lambda)}\right\rangle_{i} .
\end{aligned}
$$

We assume that $\{d \varphi, d \psi\}$ is coherent (the case of symmetric coherence is similar) and adopt the terminology of Section 2. Furthermore, we stipulate that the polynomials were normalized so that $C_{m} \equiv 1$. We define

$$
\sigma_{n}(i):=-\frac{c_{n+1} \alpha_{n+1}(i)-c_{n} x_{n}(i)}{i\left(d_{n+1}-d_{n}\right)}
$$

Thus, it follows from Theorem 2 and its corollary and from the second corollary to Theorem 3 that

$$
\begin{align*}
& p_{n+1}^{(\lambda)}-p_{n}^{(\lambda)}=\sigma_{n}\left(p_{n+1}-p_{n}\right) ;  \tag{6.1}\\
& p_{n+1}^{(\lambda)}-p_{n}^{(\lambda)}=\sigma_{n} q_{n} . \tag{6.2}
\end{align*}
$$

This are the key formulae that enable us to evaluate Fourier coefficients efficiently.

Let

$$
\left(g_{1}, g_{2}\right)_{1}:=\int_{x}^{\infty} g_{1}(x) g_{2}(x) d \varphi(x), \quad\left(h_{1}, h_{2}\right)_{2}:=\int_{-x}^{\infty} h_{1}(x) h_{2}(x) d \psi(x)
$$

where $g_{l}$ and $h_{l}$ belong to appropriate Hilbert spaces. It follows from the definition (1.3) of the Sobolev inner product that

$$
\begin{aligned}
\hat{f}_{n} & =\left(f, p_{n}^{(\lambda)}\right)_{1}+\lambda\left(f^{\prime}, p_{n}^{(\lambda) \prime}\right)_{2} \\
\hat{p}^{(\lambda)} & =\left(p_{n}^{(\lambda)}, p_{n}^{(\lambda)}\right)_{1}+\lambda\left(p_{n}^{(\lambda)}, p_{n}^{(\lambda)}\right)_{2}
\end{aligned}
$$

Multiplication of identity (6.1) by $f$ and integration yield

$$
\begin{equation*}
\left(f, p_{n+1}^{(i)}\right)_{1}=\left(f, p_{n}^{(i)}\right)_{1}+\sigma_{n}\left\{\left(f, p_{n+1}\right)_{1}-\left(f, p_{n}\right)_{1}\right\} \tag{6.3}
\end{equation*}
$$

and (6.2) similarily leads to

$$
\begin{equation*}
\left(f^{\prime}, p_{n+1}^{(i)}\right)_{2}=\left(f^{\prime}, p_{n}^{(i)}\right)_{2}+\sigma_{n}\left(f^{\prime}, q_{n}\right)_{2} \tag{6.4}
\end{equation*}
$$

Equations (6.3) and (6.4) combine into the recurrence

$$
\begin{equation*}
\hat{f}_{n+1}(\lambda)=\hat{f}_{n}(\lambda)+\sigma_{n}(\lambda)\left\{\left(f, p_{n+1}\right)_{1}-\left(f, p_{n}\right)_{1}+\lambda\left(f^{\prime}, q_{n}\right)_{2}\right\} \tag{6.5}
\end{equation*}
$$

Thus, to evaluate the $\hat{f}_{n}^{\prime}$ 's it is enough to calculate first the standard generalized Fourier coefficients $\left\{\left(f, p_{n}\right)_{1}\right\}$ and $\left\{\left(f^{\prime}, q_{n}\right)_{2}\right\}$ and then use the recursion (6.5)-there is absolutely no need whatsoever to form Sobolevorthogonal polynomials $p_{n}^{(\lambda)}$ explicitly!

To evaluate $\sigma_{n}$ with ease we either use its definition and the recursion (2.20) or combine that recursion with the identity

$$
\sigma_{n}=\sigma_{n} \quad 1-x_{n}
$$

that can be easily derived from the theory in Section 2, and the initial condition $\sigma_{0}=1$.

Another sequence that needs to be evaluated is $\left\{\dot{p}_{n}^{(\dot{)}}\right\}$, and also this task can be performed efficiently by expioiting coherence. We multiply both sides of (6.1) by $p_{n}^{(\lambda)}$ and evaluate the Sobolev inner product. Since $\left\langle p_{n+1}^{(\lambda)}, p_{n}^{(\lambda)}\right\rangle_{i}=0$, we have

$$
\begin{aligned}
\hat{p}_{n}^{(i)} & =-\sigma_{n}\left\langle p_{n+1}-p_{n}, p_{n}^{(\lambda)}\right\rangle \\
& =-\sigma_{n}\left\{\left(p_{n+1}, p_{n}^{(\lambda)}\right)_{1}-\left(p_{n}, p_{n}^{(i)}\right)_{1}+\lambda\left(q_{n}, p_{1 ;}^{(i)}\right)_{2}\right\}
\end{aligned}
$$

and

$$
\left(p_{n+1} \cdot p_{n}^{(j)}\right)_{1}=\left(q_{n}, p_{n}^{(\lambda)}\right)_{2}=0
$$

gives

$$
\begin{equation*}
\hat{p}_{n}^{(\dot{\beta})}=\sigma_{n}\left(p_{n}, p_{n}^{(\lambda)}\right)_{1} \tag{6.6}
\end{equation*}
$$

Multiplying (6.1) by $p_{n+1}$ and evaluating the $(\cdot, \cdot)_{1}$ inner product yield the identity

$$
\begin{equation*}
\left(p_{n+1}, p_{n, 1}^{(i)}\right)_{1}=\sigma_{n}\left\|p_{n+1}\right\|_{1}^{2}, \tag{6.7}
\end{equation*}
$$

since orthogonality implies that $\left(p_{n+1}, p_{n}\right)_{1}=\left(p_{n+1}, p_{n}^{(\lambda)}\right)_{1}=0$. Shift of the index in (6.7) and substitution in (6.6) give

$$
\begin{equation*}
\hat{p}_{n}^{(\lambda)}=\sigma_{n-1}(i)\left\|p_{n}\right\|^{2} \tag{6.8}
\end{equation*}
$$

To sum up, we managed to reduce the evaluation of Fourier-Sobolev coefficients to the evaluation of standard expansion coefficients with respect to $d \varphi$ and $d \psi-$ a task that is easy and safe to accomplish by virtue of orthogonality-and a simple recursion.

## Acknowi engments

The authors thank Walter Gautschi (Perduc) and André Ronveaux (Namur), who kindly provided them with many references on orthogonality in Sobolev spaces, Richard Askey (Madison) and Lance Littlejohn (Utah) for their insightful remarks, and the anonymous referees for comprehensive and helpful reviews. In particular, one of the referce's reports has been instrumental in providing unifying treatment of classical Borel measures in Section 3. They also acknowledge many uscful discussions with Brad Baxter and Martin Buhnann (Cambridge) and with Markus Hegland (Zurich).
